Blackwish gap research and evidence limits

This report advances three selected questions beyond the completed bounded examination: trauma evidence and nonresponse in Entry 046; public community perspectives and stewardship in Entry 081; and mnemonic transfer relevant to Entries 099 and 126. The new work is evidence expansion and a documentary correction, not a new governing principle or an effectiveness test of Blackwish.

What changed

A false completion condition was corrected. The earlier 081 closure added a complete-monograph requirement absent from the original note and adopted passage. The relevant question is what specified attributable sources establish, not whether an imposed publication format has been obtained. The older record remains preserved with the correction.

The evidence became more discriminating. The trauma comparison now includes different treatment packages, populations, cultural settings and response or attendance questions. Published corrections are retained rather than silently carrying forward inaccurate labels. The community sources distinguish personal testimony, Nation policy, collaborative research and publication metadata. The mnemonic checks distinguish practiced recall from prompted transfer and independent everyday use.

How to read the result

The sections keep each study or source with its population, comparator, authorship and access depth. Contrasting findings are not a vote count. A public source can answer a limited question without establishing a complete history; a useful result can remain useful without establishing every proposed explanation.

The user authorized the broader autonomous investigation on 19 October 2026, pending review for ratification. That changes the present research scope, not the history of earlier qualified completion. This report does not declare the full trauma, stewardship or learning topic finished.

A separate proposed evidence-addendum adoption unit appears on page 8. It remains pending the user's explicit decision. It is not new treatment advice, permission to start a deferred learning game, or authority for learner tests, community contact, deployment or canonical synchronization.

Different packages answer different questions

The question is what these designs can justify, not which treatment this project should prescribe. Preparation, trauma-focused work and multi-component care are not interchangeable experimental contrasts. Childhood-abuse history, complex symptoms and a specific complex-PTSD diagnosis also identify different populations.

A preliminary phase in both exposure arms

Cloitre et al. (2010) studied 104 adult women with childhood-abuse-related PTSD. Skills training followed by exposure favored some outcomes, but its exposure comparator also began with supportive counselling. The comparison therefore does not establish that preparation is always necessary before immediate trauma-focused work. Exposure was modified, and abstract versus body sustained-remission percentages disagree. No harmonized remission rate is used here.

Cloitre 2010 | Indexed publisher methods and results plus abstract; direct open failed.

Nondetection is not equivalence

Oprel et al. (2021) randomized 150 participants in a Dutch childhood-abuse PTSD trial; 149 were included after one post-randomization exclusion. Arms compared prolonged exposure, intensified exposure and skills training followed by exposure. The added-skills package had no detected overall symptom or dropout advantage through one year; the trial did not establish equivalence. Early change and later trajectories differed. Dutch fluency, exclusions, differing exposure doses and later additional care limit transport. Reported response rates used each participant's last available measurement, not one common follow-up.

Oprel 2021 | Full-text methods, results, tables and limitations inspected.

Package superiority does not identify a component

Bohus et al. (2020) studied women with childhood-abuse-related PTSD and at least three borderline-personality criteria, including affective instability. The authors' analysis included 193 after 200 randomizations. DBT-PTSD favored average symptom improvement over cognitive processing therapy at month 15, but the comparator itself included four added safety sessions. This is not an isolated test of preparation. Selected eligibility and observed-case diagnostic-remission denominators prevent a universal complex-PTSD rule.

Bohus 2020 | Full-text methods, outcomes and limitations; supplements not extracted.

STAIR denotes Skills Training in Affective and Interpersonal Regulation. PE denotes prolonged exposure; CPT denotes cognitive processing therapy; DBT-PTSD denotes dialectical behavior therapy for PTSD. These names are descriptions of the studied interventions, not instructions for their use.

Applicability is not an ethnic rule

A positive finding in one setting does not establish automatic transfer. A non-positive finding in another does not establish that its population cannot benefit. Cultural and language access matter without guaranteeing a particular symptom effect.

Adapted treatment versus delayed treatment

Hinton et al. (2005) compared initial versus delayed culturally adapted cognitive behavioral therapy in 40 Cambodian refugees with treatment-resistant PTSD and panic attacks. The abstract reports greater short-term improvement for the treated group. This supports that selected package, not the incremental effect of cultural adaptation: unadapted therapy was not the comparator. Only the original abstract was inspected; follow-up, missingness and harms were not established at that depth.

Hinton 2005 | Original PubMed abstract only.

A clustered result with a corrected measure

Bass et al. (2013) allocated 16 Congolese villages; one was excluded for a provider-competency concern. Analysis compared seven therapy villages with 157 women against eight support villages with 248 women. Symptom and function outcomes favored the therapy package. Cluster count, post-allocation exclusion, baseline differences and missing follow-up limit inference. The 65% versus 52% figures describe completion of all three assessments, not treatment completion.

Bass 2013 | Original abstract and indexed publisher methods and results.

Correction retained: the 2014 publisher correction identifies the PTSD measure as the Harvard Trauma Questionnaire, not the PCL.

Bass correction 2014 | Official publisher correction.

A real non-positive result with an implementation boundary

Buhmann et al. (2016) studied 280 refugees in a Danish factorial trial; 217 completed treatment. The implemented flexible cognitive behavioral therapy showed no detected PTSD benefit. Translation was available, but trauma-focused exposure was limited. This is not a clean test of standard exposure or proof that refugees cannot benefit. Implementation, measurement and missingness are possible contributors, not established explanations that cancel the result.

Buhmann 2016 | Publisher methods and results, limitations and selected supplement.

Correction retained: the 2024 corrigendum swaps the Therapy and Waiting-list headings in Table 2. Uncorrected arm means are not reused.

Buhmann correction 2024 | Official publisher corrigendum.

Nonresponse does not identify fault

Symptom change and attendance can rank differently

Schnurr et al. (2022) randomized 916 US veterans to prolonged exposure or cognitive processing therapy. The first had a small average symptom advantage, judged not clinically significant by the authors, but more dropout. This does not show that dropout helps. Outcomes averaged post-treatment and follow-up assessments; missing measurements and the military-care setting remain limits. Serious events causing dropout are not a complete adverse-event inventory.

Schnurr 2022 | Original abstract and indexed original results; not a full-text audit.

Group patterns do not decide an individual case

Lester et al. (2010) pooled two trials involving 94 African American and 214 White women, using the studies' racial categories. Completion differed, while intention-to-treat symptom analyses did not detect a racial difference. Race was not randomized. The result establishes neither equal access nor equivalence, a biological or cultural mechanism, or an individual prognosis.

Lester 2010 | Original abstract only.

Nixon et al. (2021) analyzed 179 female interpersonal-trauma survivors who completed cognitive processing therapy across four trials. Early models had difficulty distinguishing delayed responders from poor responders. A slow start is therefore not established final failure. Completer selection and abstract-level access do not support predictions for all patients or instructions to persist with or change anyone's care.

Nixon 2021 | Indexed original abstract; direct opening returned no article text.

Completion is not the same as clinical response

Kehle-Forbes et al. (2022) analyzed 126 retrospective interviews with US veterans, including 60 completers and 66 noncompleters. Their completion definition did not require clinical response. Accounts included therapist responsiveness, functioning and practical stressors. Purposive interviews identify reported experiences and candidate explanations, not causal probabilities for every dropout; some unavoidable or clinician-initiated endings were excluded.

Kehle-Forbes 2022 | VA-hosted original PDF, selected methods and themes.

Paper countercase: a fictional person stops attending after a work-schedule change. Attendance alone identifies neither recovery nor avoidance, misconduct or the cause of nonresponse. Benefit likewise does not prove the unique mechanism of benefit. These are logical possibilities, not patient observations or clinical advice.

Ask what a source can actually establish

The earlier completion condition was too strong

The earlier closure added a complete-monograph requirement that the original note and adopted method did not contain. This pass instead asks what specified public community sources establish about stewardship, provenance and authority. Answering that defined question does not complete the history or remove remaining source and reuse limits. This is a documentary correction, not a newly compulsory doctrine-wide standard.

Firsthand testimony is attributable rather than universal

Cascade PBS's 2024 transcript centers Stephanie Leon Riedl, identified as a Sts'ailes environmental strategist. Her account describes family or individual gathering places, ongoing tending and intergenerational purposes. It is a specific firsthand perspective in externally edited media, not every member's view. The description and transcript were read; the video was not watched. Causal suggestions and broad biodiversity assertions are not treated as measurements.

Cascade PBS 2024 | Stewarding the Land transcript.

Nation policy and a named Wilp case have distinct scopes

Sts'ailes' 2010 Cultural Heritage Resources Policy treats heritage categories as incomplete and overlapping and describes approval, continuing consultation and report review. It is a dated Nation-owned policy, not a universal Indigenous protocol or a current legal-compliance determination.

Sts’ailes 2010 | Selected heritage-policy sections.

The Nation's 2012 Environmental Stewardship Policy connects ecological care, social and economic objectives, and continuing practice. Stewardship is not presented as an automatic refusal of every development.

Sts’ailes 2012 | Selected stewardship-policy sections.

Dimdiigibuu and Armstrong (2025) pair Wilp Guutginuuxs affiliation with an explicitly identified settler collaborator. Their territorial account challenges an isolated-site archaeological framework. Consultant comparisons and legal interpretations remain the authors' account, not an independent adjudication or every House's view.

Dimdiigibuu and Armstrong 2025 | Full public article; underlying consultant reports not audited.

These sources clarify different purposes, relationships and authority. Reading them grants no permission for fieldwork, interviews, cultural-content reuse or representation. Adding a cultural-importance score cannot itself transfer authority to define that importance.

A listing is not a read book

Keep three publication stages separate

Kitselas' May 2021 newsletter announces the Traditional Plant Study, acknowledges community input and describes intended household delivery. The relevant notice establishes an intended audience and production stage, not successful delivery or the book's contents.

Kitselas Connects 2021 | Relevant notice on printed pages 12-13.

Armstrong's bibliography lists a 2022 Mitchell Press community version. That listing is a bibliographic claim, not access to the work.

Armstrong bibliography | Community-version listing inspected.

AU Press credits collaboration with Gitselasu Knowledge Holders and guidance from the Kitselas Lands and Resource Department. Its current catalog schedules the public edition for June 2027. This is a schedule, not proof of release. No book text was read, and the relationship between editions remains unverified.

AU Press catalog | Accessed 19 October 2026; book contents not accessed.

No nonpublic household copy was sought. Absence from this review proves neither absence of knowledge nor intentional withholding. Publicity, a catalog entry or an edition's license cannot be silently converted into permission to repurpose underlying knowledge.

Use is not necessarily growth at that place

Armstrong et al. (2023) note that dated food remains can reflect transported material rather than local growth, and plants on former house platforms can reflect later succession. The article also cautions against universal species-list identification and notes preservation limits. Selected methods, results and discussion were read; no data or supplement analysis was reproduced.

Armstrong et al. 2023 | Original coauthor-hosted ecological article.

A narrower model question remains possible

Continuing tending in some places and interrupted management elsewhere can coexist. Neither abundance alone nor a surviving account identifies every mechanism. A missing record does not prove no practice; public availability, preservation and editorial selection are different explanations.

Unperformed paper question: with a hypothetical species inventory held fixed, could different maintenance continuity or permitted access change the modeled household resource flow? This distinguishes presence from available harvest. No simulation, historical calibration or community-approved representation was performed.

Prompted transfer is not everyday use

No detected advantage from added virtual practice

Boller et al. (2021) randomized 48 French-speaking adults over 50 with memory complaints and without mild cognitive impairment or dementia; 40 completers were analyzed, 20 per arm. Both groups received loci training. Added virtual-reality memory practice was compared with virtual visuomotor practice, not no training. Word and virtual recall improved over time without a significant added-memory-practice advantage. This is not evidence of equivalence. Assessment denominators were 40 for words, 38 for virtual shopping, 37 for concurrent recall and road-sign detection, and 39 for an everyday-memory questionnaire. Virtual-assessment losses involved cybersickness. Road-sign detection and questionnaire change were nonsignificant. Testing ended within a week of training; there was no later durability follow-up or untreated group separating loci training from retesting. Tasks remained instructed experimental situations. The questionnaire's imperfect fit to the strategy means its null result does not prove no possible everyday benefit.

Boller and colleagues 2021 | Publisher full text; no raw-data reanalysis.

Achievers were selected and transfer tests prompted the strategy

Sandberg et al. (2023) analyzed a self-selected Swedish app cohort of 356 after two exclusions. There was no randomization or concurrent control. Transfer testing followed instruction and triggered at levels 5, 25 and 45, with the first test after passing level 4; progression allowed fewer than five errors, not perfect recall. Later analyses included 155 and 60 achievers. Higher achievers already performed better initially. Tests used face/name, face/occupation and scene/object associations, explicitly prompted loci use, and required multiple-choice responses. Reported improvement therefore concerns those tasks and selected achievers, not spontaneous daily use or understanding. Actual strategy use remained unknown. Testing times depended on progress; parallel-form validity was not established. The main analysis reports 155, while a historical-comparison paragraph says 156 despite age counts totaling 155. That discrepancy remains unresolved. No post-training durability or low-imagery subgroup efficacy was established.

Sandberg and colleagues 2023 | Full publisher HTML and PDF text; no reanalysis.

Keep the intended learning claim specific

Paper countercases: recalling a rule can coexist with applying it in the wrong situation. Applying it when prompted can coexist with failing to notice when it is relevant. Understanding an explanation can coexist with difficulty using the assessment interface. Neither study measures these invented cases.

A tool that promises only chosen-sequence recall need not establish every kind of transfer. Claims of understanding, independent application or durable everyday benefit are additional claims, not synonyms for a recall score. The deferred Encounter Foundation game design remains unstarted.

What this research now supports

Use the connections without forcing one method

Entry 046 connects relief, causal explanation, nonresponse and blame without conflating them. Entry 081 distinguishes species presence from permitted access and historical interpretation. Entries 099 and 126 connect cue, response and timing to recall, explanation and transfer in 013, 017 and 137. These are different applications, not one causal theory or compulsory workflow.

Official VA overviews recognize inadequate response after properly delivered evidence-based care and distinguish limited diagnosis-specific complex-PTSD evidence from broader PTSD studies. They are clinical guidance, not independent trials or permission for Blackwish to substitute its own protocol.

VA | Psychotherapy overview, selected sections.

VA | Complex PTSD assessment and treatment, selected sections.

What is finished and what is not

The selected public-source checks are complete at their recorded access depths. The broader questions remain qualified. Trauma still lacks an exhaustive cultural and subgroup harms synthesis, participant-level trajectories, some denominator or supplement reconciliation, and evidence of Blackwish's clinical effects. Stewardship still lacks read book contents, complete food or labor budgets and a performed simulator comparison. Mnemonic research does not establish comprehensive transfer, universal imagery accessibility or durable learning-game benefit.

This research performed no treatment, human experiment, game implementation, community contact or live revision. Further investigations can address specific missing premises without requiring every uncertainty to become a project or optional qualitative inquiry to produce a measurable payoff.

Proposed evidence addendum adoption

Pending explicit user decision. The following is a reference-material adoption unit, not a new governing rule. It is separate from the source findings and remains unadopted unless the user approves it.

Retain this reviewed evidence addendum as source-qualified reference material for entries 046, 081, 099 and 126 and their stated connections. Preserve the corrected 081 completion criterion, source identities, dates, access limits, contrary findings and remaining unknowns. The earlier qualified completion remains historical; this expansion does not declare whole-topic completion. This adopts no new governing principle and does not certify empirical truth, clinical or learning efficacy, individual suitability, community consent, deployment or canonical synchronization. Further autonomous research remains governed by the user's existing authorization; substantive future rule changes require their own explicit manual decision.

The source analysis passed historical compatibility, three distinct Zen perspectives by one reviewer, counterexample reconciliation and Death Knell, within the stated limits. This is documentary review, not empirical validation.
